Morbidity and Mortality

Weekly ·Report

U. S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE PUBLIC HEALTH SERVICE

Prepared by the

COMMUNICABLE DISEASE CENTER

634-5131

For release April 12, 1963

ATLANTA 22, GEORGIA

Vol. 12, No. 14

PROVISIONAL INFORMATION ON SELECTED NOTIFIABLE DISEASES IN THE UNITED STATES AND ON DEATHS IN SELECTED CITIES FOR WEEK ENDED APRIL 6, 1963

INFLUENZA - One or more outbreaks of influenza-like disease have now been reported from 41 States and the District of Columbia. The State of Utah was the only one to report outbreaks for the first time this week. Influenza A2 virus has been isolated or confirmed by serologic titer rise as the causative agent of one or more outbreaks in 32 States and the District of Columbia. States reporting confirmed outbreaks for the first time this week are Indana and Montana. Outbreaks are continuing to subside in most affected areas in the Eastern and Middle Western United States, without evidence of further significant involvement of the Pacific Coast region. The number of

pneumonia-influenza deaths reported for 108 cities this week continued to fall sharply for the third consecutive week following the peak reached during the week ending March 16.

Florida - Serologic confirmation of influenza A₂ infection was obtained in eight sporadic cases seen in Dade County during the month of February. No outbreaks of influenza-like illness have been reported in the State during the current season.

(Reported by Wilson T. 94) Health Office and Clarence of Preventable Disease, Florida

M.D., M.P.H., State burp, M.D., Bureau of Board of Health).

APR 1963

---	----------------------	--	---------------------------

Indiana – A small community outbreak of laboratory confirmed type A_2 influenza occurred in Johnson County in central Indiana during late February and early March. The disease was described as somewhat milder than that of previous Asian influenza epidemics. The outbreak was not accompanied by unusual school absenteeism. Four of six sets of paired sera obtained from typical cases demonstrated significant titer rises to the A_2 antigen. One additional sporadic case, from Wells County, in the northeastem part of the State has recently been confirmed serologically as influenza A_2 .

(Reported by Dr. A. L. Marshall, Jr., Director, Division of Communicable Disease Control, Indiana State Board of Health).

Mantona - The outbreak of acute febrile respiratory disease reported from Eureka, Lincoln County, in February (MMWR Vol. 12, No. 9) has been confirmed serologically as influenza A2 in two cases. No new outbreaks were reported in the State during the past week.

(Reported by Dr. Mary E. Soules, Director, Disease Control, Montana State Board of Health.)

Ohio - Influenza A₂ virus has been confirmed as the etiologic agent in outbreaks of acute febrile respiratory disease observed in the Cleveland metropolitan area earlier this year. It has been estimated that in excess of 2500 cases, representing all age groups, occurred during the epidemic period which began in mid-January, reached its peak some time in February, and now appears to be subsiding.

(Reported by Dr. Winslow Bashe, Division of Communicable Diseases, Ohio Department of Health.)

Utah - Small community outbreaks of influenza-like illness were reported from two rural counties in southern Utah (Beaver and San Juan) during the week ending April 6. San Juan County, in the southeastern corner of the State, lies adjacent to sites of recent confirmed influenza outbreaks in Apache and Navajo Counties in Arizona. One serologically confirmed case has been reported from San Juan County thus far. In addition, influenza A2 virus has been isolated from 3 sporadic cases in Salt Lake County, and one sporadic case in Cache County in the northern part of the State has been confirmed serologically.

(Reported by Dr. A. A. Jenkins, Director, Communicable and Chronic Disease, Section, Utah State Department of Health.)

Wisconsin - Type A₂ influenza has been confirmed serologically in 19 sporadic cases representing 13 counties from several geographic regions within the State. No new outbreaks of influenza-like illness have been reported.

(Reported by Dr. Josef Preizler, Director, Bureau of Communicable Diseases, Wisconsin State Board of Health.)

RABIES TRENDS - 1962

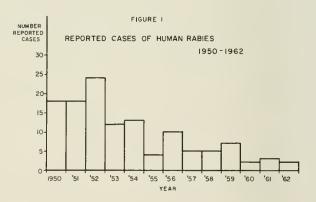

Reports from the States indicate that the occurrence of human and animal rabies infections has remained essentially unchanged since 1960. Figure 1 illustrates the annual occurrence of reported human rabies for the period 1950-1962, while Figure 2 similarly portrays the annual occurrence of reported animal rabies for the same period.

Human Rabies — Only two human rabies deaths were recorded in the United States in 1962, both in children not receiving treatment. Pertinent information for each of these patients is summarized in the table below:

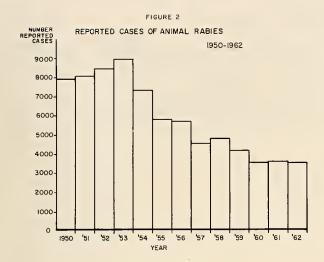

U. S. HUMAN RABIES DEATHS

Locality	Dote Died	Age	Sex	Noture of Exposure	Incubation Period	Length of Illness	Treatment	Biting Animal
Comeron County, Texos	7/24/ 62	4	М	Unknown	Unknown	11 doys	None	Unknown probobly dog
Coribou County, Idoho	10/8/	11	N	Bitten on cheek	3 or 4 weeks	4 doys	None	Unidenti- fied; possibly bot

This number is consistent with the occurrence of reported human rabies cases for the previous two years and is below the average annual occurrence of 11.6 cases observed during the period 1950-1959.

Animal Robies - The preliminary total of 3,550 reported cases of animal rabies in 1962 represents a slight decrease of 49 cases from the 1961 total. The East North Central States experienced a substantial increase in animal rabies cases as a result of increases in Ohio, Indiana, and Wisconsin. A severe outbreak of skunk rabies in Ohio resulted in an increase from 79 cases in 1961 to 380 cases in 1962. Illinois reports a marked fall in rabies from 163 in 1961 to 93 in 1962. Michigan also observed a decrease in reported cases.

Increases were noted in the West North Central, East South Central, Middle Atlantic and Pacific areas. Minnesota attributed their increase of 79 cases to an increase in skunk rabies and California's increase of 31 cases was attributable to an outbreak of dog rabies along the Mexican border in the vicinity of Tia Juana. In the western States Nevada reported its first case of fox rabies in 30 years.

The West South Central area showed a sharp decline in reported cases. In Arkansas, cases decreased from 246 in 1961 to 70 in 1962, while Texas recorded a 175 case decrease from the 1961 total.

The South Atlantic area also showed a general decrease although raccoon rabies, which has been endemic in Florida for many years was reported in Georgia in 1962.

EPIDEMIOLOGICAL REPORTS

Typhoid Fever – One additional case of typhoid fever in an individual returning from Zermatt, Switzerland, was reported this past week from New York City. This patient developed an illness on February 13, two days before arrival in Zermatt. She remained in Zermatt until February 25 and then returned to New York, where a stool culture yielded S. typhi, phage type as yet unidentified.

Case number 9 reported last week a 32-year-old male from New York City who visited Zermatt between March 8 and 19, with onset of illness on March 12, was originally confirmed by stool culture reported as S. typhi. Subsequent laboratory examination has identified the isolate as a Shigella species. The total reported cases in the U. S.

(Continued on page 120)

Pneumania-influenza martality – The number of pneumonia-influenza deaths reported in 108 cities continues to decline. For the week ending April 6, the number reported was 618, an excess of 109.

Every division reported a decline including the Pacific and Mountain States which last week reported increases.

Excess deaths from all causes declined from 873 last week to 321.

Comporison with 1960 A₂ Epidemic – Cumulative excess mortality since the week ending January 5th is compared with the 1960 data in the following table:

Four-week overage - pneumonia-influenzo mortality - As seen in the accompanying table and chart, the average number of pneumonia and influenza deaths during the four-week period ending April 6 showed a decline.

PNEUMONIA AND INFLUENZA DEATHS

traced to Zermatt now stand at eight, with one additional case reported with onset of illness before arrival in Zermatt.

(Reported by Dr. Tibor Fodor, Epidemiologist, Bureau of Preventable Diseases, New York City Health Department).

Typhoid Fever - Los Angeles, Californio

A chicken salad partly prepared by a 51-year-old retired chef for his granddaughter's birthday party was responsible for 8 confirmed and 6 suspected cases of typhoid fever in the Los Angeles area.

The party was held in a private home in Pacoima, California, on February 16. It was attended by 83 persons, who were mostly high school students. The first clinical illness began on February 21. The existence of the epidemic was not suspected, however, until 2 persons with fever and symptoms of gastroenteritis were admitted to a private hospital on March 10. Widal tests showed both had high titers. These two patients were then transferred to the Los Angeles General Hospital with a presumptive diagnosis of typhoid fever.

Following recognition of the disease, the Los Angeles County Health Department contacted all persons who had attended the party. Sixteen individuals were found to have symptoms suggestive of typhoid fever and were admitted to Los Angeles General Hospital. Of these, eight patients have had confirmatory evidence, while two were discharged with a diagnosis of febrile illness other than typhoid fever. The remaining six are still under observation. Incubation periods in the confirmed cases ranged from 5 to 24 days.

Three of the cases were younger children who did not attend the birthday party but ate in their own homes some of the chicken salad served at the party.

Salmonella typhi has been isolated from stool specimens submitted by the grandfather. He has no history of typhoid fever, but did have "trouble with gallstones" in 1935. He worked as a food handler and cook from 1955 through 1962.

For control purposes, the Los Angeles City Health Department obtained two stool specimens one week apart from each person who attended the party. Family contacts of diagnosed cases were immunized against typhoid fever and have been kept under surveillance for 35 days.

(Reported by Philip K. Condit, M.D., Chief, Bureau of Communicable Diseases. State of California Department of Public Health.)

INTERNATIONAL NOTES - QUARANTINE MEASURES Ploque - Son Froncisco

The Division of Foreign Quarantine on March 29, 1963, declared uninfected the local area in San Francisco described for rodent plague (MMWR, March 15, 1963). An intensive program of investigations and rat trapping revealed no additional evidence of infected animals.
